EES 4760/5760

Agent-Based and Individual-Based Computational Modeling

Jonathan Gilligan

Class #13: Wednesday, October 02 2024

Getting Started

- Sit with your team partners
- Download model:
 - https://ees4760.jonathangilligan.org/models/class_12/business-investor.nlogo

Subsetting

Subsetting

- Open the BusinessInvestor model in NetLogo
- Click `setup`
- Turn all the turtles red and the patches black
- Turn turtle 5 yellow and move it to `patch 0 0`
- Ask turtle 5 to identify all the patches that are exactly 2 patches away from the turtle's patch (not a 2-patch radius from turtle-2)

Hints:

- There are many ways to do this. Let's look at a way to do this with the `neighbors` primitive.
- Hints:
 - Use `member?` primitive (`member <agent> <agent-set>`)
 - Use `patch-set` primitive to turn an list of many patch-sets into a single patch-set
- Suggestion:
 1. Start by turning all neighbor patches (patches exactly 1 patch away) blue
 2. Next turn all patches within 2 patches blue
 3. Now turn all patches black again
 4. Now turn all patches within a 2-patch distance blue *except* the turtle's patch
 5. Now turn all patches black again
 6. Now turn all patches within a 2-patch distance blue *except* the turtle's patch and the patches 1 patch away.

A solution

```
ask turtle 5 [  
  ask (patch-set [neighbors] of [neighbors] of self) with  
    [not member? self [(patch-set neighbors patch-here)] of myself]  
  [  
    set pcolor blue  
  ]  
]
```

- What does `self` refer to in `patch-set [neighbors] of [neighbors] of self`?
 - `self` refers to `turtle 5`
 - `ask turtle 5 [...]` puts the `[...]` in the context of `turtle 5`, so `self` refers to `turtle 5`
- What does `self` refer to in `not member? self [(patch-set neighbors patch-here)] of myself`?
 - `self` refers to the various patches in the `patch-set`: `(patch-set [neighbors] of [neighbors] of self)`
 - `x with [...]`, where `x` is an `agent-set` evaluates `[...]` for each of the agents (patches, turtles, links) in `x`, so `self` in the `[...]` refers, in turn, to each patch in the `patch-set`
- What does `myself` refer to in `not member? self [(patch-set neighbors patch-here)] of myself`?
 - `myself` refers to `turtle 5`
 - `myself` refers to the agent doing the asking

Self vs. Myself

```
to test-self-myself
  ask turtle 5
  [
    ask turtle 7
    [
      print (word "first self = " self)
      print (word "first myself = " myself)
      ask turtle 2
      [
        print (word "second self = " self)
        print (word "second myself = "
myself)
      ]
    ]
  ]
end
```

```
observer> test-self-myself
```

```
first self = (turtle 7)
first myself = (turtle 5)
second self = (turtle 2)
second myself = (turtle 7)
```

Telemarketer Model

- `self` refers to the agent *being asked*.
- `myself` refers to the agent *doing the asking*.
- First: `turtle 5` is asking `turtle 7` to do something.
 - `self` is `turtle 7`, `myself` is `turtle 5`
- Second: `turtle 7` is asking `turtle 2` to do something.
 - `self` is `turtle 2`, `myself` is `turtle 7`

Telemarketer Model

- Telemarketing firms interact
 - Telemarketer calls patches
 - If patch has received a previous call that tick, it hangs up
 - If patch has not received a previous call that tick, it buys something
 - Interaction is indirect, mediated by patches
- Accounting:
 - $\text{Net profit} = 2 \times \text{sales} - 50 \times \text{size}$
 - If $\text{balance} < 0$, firm goes bankrupt
- Growth
 - If $\text{balance} > \text{growth threshold}$, firm increases size proportional to excess balance

Median Weeks in Business

How to Calculate Median Weeks in Business?

- There are 50–500 telemarketers (turtles)
- What happens when a telemarketer goes out of business?
- What do you need, to calculate a median?
- We need a list of how long each turtle survives
- Use NetLogo `list` primitive in a global variable
- How do you figure out the age of a turtle in this model?
- How might we update the list? (Hint: consult the NetLogo dictionary)
 - You may want to use the `replace-item` primitive
 - See the “Lists” section in the NetLogo Programming Guide in the User Manual for more guidance on how to update lists.

Mergers

Mergers

- Instead of going bankrupt when the bank balance drops below 0, firms look for acquisition partner
 - Find a company that's bigger and has enough money to pay off deficit.
 - If it finds a parent, parent pays off deficit (child firm ends up with 0 balance)
 - In future turns, child pays parent 50% of its net profits.
 - In future, if child's balance becomes negative:
 - If parent has enough money, it pays child's deficit
 - If parent does not have enough money, child dies.
